

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

UNITED STATES PATENT APPLICATION FOR:

NETWORK ENABLED BIOFEEDBACK ADMINISTRATION

Inventor: Thomas F. Collura

Theresia A. Mrklas

Date Filed:

Express Mail Label No. *EL37915815645*

Attorney Docket No. 73546/06356

555532.1

EXPRESS MAIL
1 APR 1991 NO. EL 37915815045

(A) TITLE OF THE INVENTION

NETWORK ENABLED BIOFEEDBACK ADMINISTRATION

(B) CROSS-REFERENCE TO RELATED APPLICATIONS.

Not applicable.

(C) STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT.

Not applicable.

(D) REFERENCE TO A "MICROFICHE APPENDIX."

Not applicable.

(E) BACKGROUND OF THE INVENTION

(1) FIELD OF THE INVENTION.

The present invention pertains generally to EEG biofeedback for learning and controlling bio-electric characteristics of the brain which correspond to different mind states and more particularly to an apparatus and method for reducing stress in a human subject through the production of soothing audio, visual and other sensory effects that is capable of being monitored or modified at a remote location.

(2) DESCRIPTION OF THE RELATED ART INCLUDING INFORMATION

DISCLOSED UNDER 37 CFR 1.97 AND 37 CFR 1.98.

1
5 EEG (brainwave) signals have been extensively studied in an effort to determine relationships between frequencies of electrical activity or neural discharge patterns of the brain and corresponding mental, emotional or cognitive states. Biofeedback of identified frequency bands of EEG signals is used to enable a person to voluntarily reach or maintain a target mental state.

Frequency bands of EEG readings used in such biofeedback have been generally categorized in the approximate frequency ranges of:

delta waves, 0 to 4 Hz;

theta waves, 4 to 7 Hz;

10 alpha waves, 8 to 12 Hz;

beta waves, 12 Hz to 36 Hz, and

sensorimotor rhythm (SMR) waves, 12 to 15 Hz.

It is theorized that each of the major subbands of biofeedback EEG (delta, theta, alpha, beta) has unique bio-electric characteristics which correspond with unique subjective characteristics of an individual. The delta band is observed most clearly in coma and deep sleep, the theta band in light sleep and drowsiness, the alpha band in a variety of wakeful states involving creativity, calm and inner awareness, and the beta band in alert wakeful situations with external focus. In general, a dominant brain wave frequency increases with increasing mental activity.

20 Biofeedback systems are well known in the art for use in detecting levels of stress in subjects and providing the appropriate stimuli to affect and alter the flow of brain wave patterns. The biofeedback system monitors and processes bioelectrical signals generated in specific topological regions of a subject's nervous system and produces a sensory stimulus if the system detects the presence or absence of certain characteristics in the signal's wave form patterns. These characteristics may be correlated with a certain desired condition of the subject's nervous system. The sensory stimulus provided by the biofeedback system, typically an audio or visual stimulus, or combination thereof, is fed back to the subject which associates the presence of the stimulus with the goal of achieving the desired condition of its nervous system. By responding to the stimulus, the subject can be trained to control the waveform

patterns of the monitored bioelectrical signals and thereby control his or her own nervous system. Such a system is illustrated in U.S. Pat. No. 3,727,616 to Ross.

Many different approaches have been taken to EEG biofeedback to achieve mental state control. U.S. Pat. No. 4,928,704 describes a biofeedback method and system for training a person to develop useful degrees of voluntary control of EEG activity. EEG sensors are attached to cortical sites on the head for sensing EEG signals in a controlled environmental chamber. The signals are amplified and filtered in accordance with strict criteria for processing within time constraints matching natural neurologic activity. The signals are filtered in the pre-defined sub-bands of alpha, theta, beta and delta, and fed back to the monitored person in the form of optical, aural or tactile stimuli

Because biofeedback devices operate on the basis of internal stimuli, that is, stimuli produced in response to bioelectrical signals generated by the subject, the success of the true biofeedback device is dependent upon a subject attempting to consciously control his or her state of stress. Many people cannot effect such control over their involuntary nervous systems.

U.S. Patent No. 5,304,112 to Mrklas et al. and U.S. Patent No. 5,899,867 to Collura, both of which are incorporated herein by reference, each disclose a standalone, computerized system wherein a single user's mental activity is monitored by a computer which provides feedback to the user corresponding to the monitored mental activity. In addition to the user using the equipment, a monitor such as a therapist or health care provider may also be present.

A limitation of these systems is that all communications and control functions are located in a single microprocessor and the user, monitor and all data acquisition and computing equipment must be in the same proximity, and can not be spatially separated. Additionally, all data and resources available to the diagnostic, therapeutic, and training systems must also be located in close proximity to the system. It is necessary to deploy hardware and software in such a manner that complete autonomous offices are established. Presently, there is no capability to distribute processing, control, resources, or expertise between or among the various systems.

A drawback to the current systems is that a professional desirous of monitoring a session must travel to the user's location, or the user must travel to the professional's location. This may not always be convenient, practical, or even possible. Thus, the current systems are

limited in the availability of training and services available.

Therefore, the need exists for a system which can facilitate distribution of functions and services to local and remote locations in such a manner that an expert diagnostic and therapeutic practitioner can administer care to an individual user from a remote location. Data which may be transmitted to the remote location includes, but is not limited to medical monitoring devices, biofeedback and neurofeedback devices, blood pressure, bio-electric devices, heart monitors, and medication dispensers and pumps.

Additional objects, advantages and novel features of the invention will be set forth in part in the description which follows, and in part will become apparent to those skilled in the art upon examination of the following or may be learned by practice of the invention. The objects and advantages of the invention may be realized and attained by means of instrumentalities and combinations particularly pointed out in the appended claims.

(F) BRIEF SUMMARY OF THE INVENTION

In view of the aforementioned needs, the invention contemplates a system that distributes functions and services in such a manner that an expert diagnostic and therapeutic practitioner can monitor and administer a user's session from a remote location while the user simultaneously receives instant feedback from computerized diagnostic and therapeutic equipment at the user's location.

Input means receives data from the user. The input means may be comprised of video, audio, or physiological sensors. Many physiological sensors are common in biofeedback applications, including but not limited to an encephalograph that measures electrical potentials on the scalp and generates a record of the electrical activity of the brain ("EEG"); a cardiograph which is used in the detection and diagnosis of heart abnormalities that measures electrical potentials on the body surface and generates a record of the electrical currents associated with heart muscle activity ("EKG"); an electromyograph ("EMG") that senses the electrical activity of a muscle and optionally makes a graphic record; or a galvanic skin response meter that measures galvanic skin response ("GSR") that is a change in the ability of the skin to conduct electricity, caused by an emotional stimulus, such as fright.

Furthermore, the input means may be comprised of a combination of video, audio, and physiological sensors.

The user receives output from a feedback means which can expose the user to a plurality of sensory phenomena. Similar to the input means, the typical feedback means outputs video, audio, or physiological stimulation. For video feedback, often a light pattern is displayed on a monitor or television screen wherein the shape of the pattern or intensity of the light is varied. For audio stimulation, speakers or headphones may be used to projecting various sounds or music. Electrical stimulation, tactile stimulation such as vibration or pressure, thermal stimulation, or olfactory stimulation also may be used for providing physiological feedback. The various methods of providing feedback may be used alone or in any combination thereof.

A local computer is connected between the input means and feedback means. The local computer receives the input from the input means, process the data and produces an output which is sent to the feedback means. Additionally, the user may be provided with controls at the local computer to adjust the feedback.

A remote computer is connected to the local computer, providing additional control and analysis of the biofeedback session from a remote location. The remote computer would be connected to the local computer over either a wired or wireless network. In the preferred embodiment, the Internet would be utilized for communications between the remote and local computers. The remote computer would be capable of outputting session information to a monitor at the remote location. The session information could be either the input data being received by the input means, the output being produced by the local computer, or a combination of both. Optionally, the monitor can select which session parameters are output. For example physiological data may be displayed on a monitor, alternatively a video of the session may be played simultaneously with the physiological data, and audio of the session may also be output. The remote computer would have means connected to it for receiving input from the monitor, enabling the monitor to adjust the parameters of the session. The remote computer would communicate the input from the monitor to the local computer which could then adjust output being sent to the feedback or modify or change the input parameters

being input into the system.

Additionally, the remote means has additional software for monitoring the session. The remote software may perform more intense computations or process long term trends. Based on the results of the computations, the software on the remote computer can adjust session parameters, such as the output from the local computer.

By utilizing a combination of remote software and remote input and output means, a single monitor may simultaneously monitor a plurality of sessions. This could enable a group session. Optionally, the monitor may select certain parameters causing the remote software to activate an alarm based on specified parameters.

In an alternative embodiment, the remote processor only has one feedback loop. This feedback loop, comprised of software only would perform long term trending an analysis. This would enable biofeedback session to occur when no monitor is available. This could also enable a plurality of local computers to communicate to a single remote computer, wherein the remote computer would contain more sophisticated software for more intensive data analysis which may be performed either real time or in a batch mode of operation. The remote computer, after performing the additional calculations or analysis, could then adjust session parameters for a particular user. Additionally, a database at the remote computer may be utilized to store session information and various parameters changes which can be reviewed by a professional at a later time.

In yet another embodiment of the invention, the remote computer would be capable of remote outputting of session data and remote inputting of system parameter changes by the monitor. In this embodiment, only the monitor would adjust the system parameters from the remote location. This embodiment may be useful for short term group therapy sessions where long term trending an analysis is not necessary. This embodiment is also useful where a professional wishes to monitor a user from a long distance, but does not desire to spend the extra costs for additional computing resources.

In still yet another embodiment of the present invention, a user would utilize a local computer connected to the input means and feedback means, a first remote computer, and a second remote computer. The three computers would be interconnected either by a wired or

1
f

wireless network, preferably the Internet. The first remote computer having software for monitoring a biofeedback session and capable of adjusting the output of the local computer, and ultimately the feedback received by the user. The second remote computer having remote input means and remote output means enabling a monitor from a location spatially separated
5 from the local computer and first remote computer to observe the session and make adjustments. Optionally, the second remote computer would have additional software for analyzing and adjusting the local computer output. This embodiment would be useful in a case where a health care provider desires utilize a plurality of local computers for biofeedback sessions and a plurality of monitors for monitoring the sessions. By utilizing this
10 arrangement, one monitor may be able to consult with a second monitor who can also analyze and control the biofeedback session. Furthermore, the health care provider can make either global changes to all of the local computers or incremental changes to a particular session from the first remote computer.

The present invention also contemplates a method for controlling a biofeedback
15 session utilizing a distributed biofeedback system. The process begins by receiving data from a user. The data may be video, audio, or physiological. This data is then processed at a local computer which produces a local feedback output based on the data. The data is also sent to another computer at a remote location. Further analysis of the data is performed at the remote location. Based on analysis of the data at the remote location, the local feedback output at the
20 local computer can be adjusted. The feedback is then communicated to the user.

Among those benefits and improvements that have been disclosed, other
objects and advantages of this invention will become apparent from the following description taken in conjunction with the accompanying drawings. The drawings constitute a part of this specification and include exemplary embodiments of the present invention and illustrate
25 various objects and features thereof.

(G) BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

The drawings illustrate the best mode presently contemplated of carrying out the

invention.

The drawings:

FIG. 1 is a schematic representation of the hardware components of the system of the present invention;

FIG. 2 is a schematic representation of the hardware components of an alternative embodiment of the system of the present invention;

FIG. 3 is a detailed block diagram of the hardware components of the present invention;

FIG. 4 is a detailed block diagram of the hardware components of an alternative embodiment of the present invention.

(H) DETAILED DESCRIPTION OF INVENTION

With reference to FIG. 1, there is illustrated the basic components necessary for a biofeedback session utilizing the system of the present invention. The system includes a user interface device 10. The user interface device 10 is comprised of various components for receiving input from a user 16, a processor ("local processor") for processing the input and producing an output which is received by the user 16. The user interface device 10 has communications means 12, usually either a modem or network interface card for connecting to a network 14. The typical connection between the communications means 12 and the network 14 would include cabling, however, in the case of wireless networks the connection may be made by radio or optical waves.

Similarly, at a remote location is a remote interface device 20. The remote interface device 20 has means which allows a service professional or session monitor 18 to monitor the biofeedback session. The remote interface device 20 is comprised of various components for outputting data received by the user interface device 10 to the session monitor 18, and for receiving input from the session monitor 18. The remote interface device 20 has

communications means **22**, usually either a modem or network interface card for connecting to a network **14**. The typical connection between the communications means **22** and the network **14** would include cabling, however, in the case of wireless networks the connection may be made by radio or optical waves with the appropriate transceivers located at the communications means **12** and the network **14**.

The network **14** connecting the user interface device **10** to the remote interface device **20** may be comprised of a plurality of local area networks and in the preferred embodiment would utilize the Internet. By utilizing the Internet, the user interface device **10** and the remote interface device **20** may be spatially segregated by hundreds or thousands of miles.

With reference to FIG. 2 is shown an alternative embodiment of the present invention. This embodiment includes the addition of a secondary remote device **30**. The secondary remote device **30** is also connected to the network **14** by communications means **32**, usually either a modem or network interface card for connecting to a network **14**. Similarly, the typical connection between the communications means **32** and the network **14** would include cabling or in the case of wireless networks the connection may be made by radio or optical waves. As will be described further, the secondary remote device **30** also receives all results from the user interface device **10**. The secondary remote device **30** can provide additional monitoring or diagnostics of the biofeedback session.

Now referring to FIG. 3, a more detailed description of the various hardware components of the present invention are illustrated. A user **16** is connected to a user interface device **10** through the input means **34** and the feedback means **36**. Once the user is connected to the input means **34** and feedback means **36**, a biofeedback session is initiated. The input means **34** connected to the user **16** may be comprised of video, audio, or physiological sensors. Many physiological sensors are common in biofeedback applications, including but not limited to an encephalograph that measures electrical potentials on the scalp and generates a record of the electrical activity of the brain ("EEG"); a cardiograph which is used in the detection and diagnosis of heart abnormalities that measures electrical potentials on the body surface and generates a record of the electrical currents associated with heart muscle activity ("EKG"); an electromyograph ("EMG") that senses the electrical activity of a muscle

and optionally makes a graphic record; or a galvanic skin response meter that measures galvanic skins response (“GSR”) that is a change in the ability of the skin to conduct electricity, caused by an emotional stimulus, such as fright. Furthermore, the input means may be comprised of a combination of video, audio, and physiological sensors.

5 The user **16** receives output from a feedback means **36** which can expose the user to a plurality of sensory phenomena. Similar to the input means, the typical feedback means outputs video, audio, or physiological stimulation. For video feedback, often a light pattern is displayed on a monitor or television screen wherein the shape of the pattern or intensity of the light is varied. For audio stimulation, speakers or headphones may be used to projecting
10 various sounds or music. Electrical stimulation, tactile stimulation such as vibration or pressure, thermal stimulation, or olfactory stimulation may also be used for providing physiological feedback. The various methods of providing feedback may be used alone or in any combination thereof.

 The user interface device **10** is comprised of a computer processor with a plurality of
15 processing nodes. This processor is local to the user and is often referred to as the local processor. The processing nodes provide specific processing capabilities. The user interface device **10** also has a local database **38** for storage and retrieval of data received or output from the various nodes and is connected to the network **14** for communications with the remote processor.

20 The input node **1** of the user interface device **10** receives the data from the input means **34**. The input node performs the functions of data acquisition, antialiasing, scaling and shifting of the data received, and artifact rejection. For example, a typical situation for artifact rejection is where an evoked neural response is contaminated by occasional bursts of muscle activity when the subject fidgets.

25 A primary feedback node **2** of the user interface device **10** produces an output suitable to control the feedback means **36** based on its inputs. The output is communicated to the feedback means **36**. One of the inputs **46b** to the primary feedback node **2** is from the input node **1**. This enables the user **16** to receive physiological data in a simple, direct manner via the feedback means **36**. For example, EKG, EEG or heartbeat readings may be displayed on a

computer display terminal without any data analysis being performed. Other outputs which may be produced by the primary feedback node **2** include, but are not limited to, pitch and amplitude of sounds; motion, size and shapes of displays; progress of animation; presence of objects; and/or attributes of objects.

5 The user interface device **10** also has a first-level data node **3**. The first-level data node receives data from the primary input node **1** and performs some data manipulation. Some of the functions which may be performed by the first-level data node **3** are generation of fast fourier transforms or other spectral analysis; digital filtering; artifact rejection; signal averaging; coherence and phase measurement; and computation of derived quantities such as
10 rations, proportions and durations. The first-level data node **3** also prepares and sends data packets over the network **14** to the remote interface device **20**.

15 The first-level feedback node **4** provides for more complex feedback being received by the user **16**. The first-level feedback node **4** receives data from the first-level data node as well from the remote interface device **20**. The first-level feedback node **4** provides decisions based on threshold settings, decisions based on protocol settings, decisions based on timing and duration of signal parameters and produces outputs providing scaling, and amplitude information as well as decisions for display attributes. In addition, the output of the first-level feedback node **4** may be controlled by the remote interface device **20**.

20 The remote interface device **20** is connected across the network **14** to the user interface device **10**. The remote interface device **20** also has a computer processor, that has a plurality of processing nodes. Because this processor is located at a location remote from the user **16**, it is often referred to as a remote processor. The remote interface device **20** has a remote database **44** for storage and retrieval of data received or sent from the remote interface device **20**.

25 The remote input node **5** receives data packets from the remote interface device **10**. More specifically, the remote input node **5** receives data packets from the first-level input node **3**. A remote feedback node **6** receives the input from the remote input node **5** and generates an additional output which is sent across the network **14** to the first-level feedback node **4** which can ultimately results in additional inputs used by the primary feedback node **2**

to generate the output being used to control the feedback means **36**. Thus, more sophisticated or specialized software at the remote location may be utilized for providing additional feedback to the biofeedback session. This also enables archived data and/or expert systems to be incorporated into the feedback session. In addition, data may be shared among a group of remote interface devices **10** to simulate a group session.

A second remote input node **7** receives data from the input node **5** in preparation of presenting the data at the remote location for monitoring by a session monitor **18**. The second remote input node **7** extracts trend or other high level data from the remote input node **5**. The second remote input node **7** may interact with a database containing normative data or rules and allow more detailed analysis of current performance of the biofeedback session. One output of the second remote input node **7** goes to the remote output means **40**. The remote output means **40** communicates biofeedback session data to the session monitor **18**. In addition to displaying charts and graphs of the various physiological data received by the input means **34**, the remote output means **40** may display more specialized analysis generated by software at the remote interface device **20** such as trending. Furthermore, the remote display means may include speakers for audio output or a video output enabling the session monitor **18** to listen, watch or otherwise observe the user **16**. Furthermore, the remote display means **42** is capable of retrieving data from either the remote database **44** or local database **38**.

The session monitor **18** may adjust the system parameters, and ultimately the feedback means **36** by utilizing the remote input means **42**. Typically the remote input means **42** would comprise a keyboard and mouse connected to a computer which displays available or currently selected options. The remote input means **42** may also utilize video or audio inputs as well. The adjustments made by the session monitor **18** at the remote input means **42** is communicated to the secondary remote input node **8**. The secondary input node **8** in addition to receiving data input by the session monitor **18**, integrates analysis and data received from the secondary remote input node **7**, and produces an output. The output from the secondary remote feedback node **8** is sent to the remote feedback node **6** which controls the output of the remote feedback node **6**. The output of remote feedback node **6** is then sent to the first-level feedback node **4**, adjusting the output of the first-level feedback node **4** which is then sent to

feedback node 2, adjusting the output of feedback node 2 which controls feedback means 36.

The operation of the system can be understood in terms of functional control loops. Each control loop has a particular set of response delay characteristics and corresponding data processing and manipulation characteristics. Loops with longer response times would have
5 higher level or more sophisticated functions. Thus, a system which combines highly trained human professional personnel as well as high-level computer processing elements can be attained.

The first control loop, the primary local loop, the path shown as 46a, 46b and 46c, is comprised of the input means 34, the primary input node 1, the primary feedback node 2, the
10 feedback means 36. This loop has a characteristic response time of 1 to 100 milliseconds. This loop has the ability to make simple determinations of signal parameters based upon analysis of input signal characteristics. While the parameters of this loop may be set by an adaptive system at a higher level, this loop would not include adaptive processing of its own.

The primary control loop by itself is a simple biofeedback loop. Physiological data
15 from this loop are made available in a simple, direct manner so that the subject can become aware of them.

The secondary local loop, adds the nodes connected by 47a, 47b, and 47c to 46a and 46c. This loop receives input from the primary input node 1 and produces an output that is feedback into the primary feedback node 2. When only the primary control loop and
20 secondary control loop are used, then a system of the type described in U.S. Patent No. 5,899,867 is produced. This provides functions suitable for self-administration of biofeedback training.

This loop has a characteristic response time from 100 to 1000 milliseconds. It includes control methods that extract information from the input such as FFT, digital filtering,
25 autoregressive, or related methods. The time delay introduced by these methods is based upon the requirement to analyze an epoch, or extended duration of the input signal, in order to generate the output information. Delays are encountered in various forms, including the need to process epochs in discrete "chunks," delays inherent in band-pass or low-pass filtering, time necessary to compute adaptive parameters such as percent time over-threshold and average

power, etc. They are not introduced by any particular processing limitations on hardware platform. The delays are inherent in the calculations, and would be present even if the hardware were infinitely fast. Certain functions could introduce very long delays, on the order of one to ten seconds, such as adaptive thresholding methods that require such an extent of historical data in order to compute values.

The primary remote loop introduces the new elements along the path shown as **48a**, **48b**, and **48c**. The complete path for this loop is **46a**, **47a**, **48a**, **48b**, **48c**, **47c**, **46c**. The connections across **48a** and **48c** are across a network or other long distance communication. In the preferred embodiment, **48a** and **48c** would occur across the Internet, allowing a spatial separation of hundreds or thousands of miles if desired.

This loop introduces an additional layer of control, mediated by a privileged, or highly capable remote processor. Typical functions provided by this level would include access to archival or normative data, use of proprietary algorithms, application of specialized or costly software algorithms, and use of licensed material. The characteristic response times would be in the range of 100 to 1000 milliseconds, based upon a combination of factors which would consist primarily of communication delays between the local and remote processors and access and processing delays incurred within the remote processor.

With the addition of the primary remote loop to the primary local loop and secondary local loop, a system is created wherein a remote service provider can provide additional control and analysis of the biofeedback session. The additional control can be provided by the use of specific software, databases, and other operational facilities. It also provides the possibility of using archived data and/or expert systems, or of sharing data and/or feedback sessions. This loop also provides the capability to simulate a group situation using the communications network to facilitate the experience.

The secondary remote input loop includes the additional elements along the path of **49a**, **50a**, **50b** and **49c**. The entire path of this loop is **46a**, **47a**, **48a**, **49a**, **50a**, **50b**, **49c**, **48c**, **47c**, and **46c**. This loop communicates with the remote display means **40** and the remote input means **42**.

The addition of this loop gives the system the additional capability of allowing an

expert user, such as a technician or therapist, to interact with the biofeedback session. The session monitor **18** will have access to comprehensive information derived from the local processor **10** including telemetry, video, audio, and processed versions thereof, an informative and interactive display. With the introduction of this level of control, executive decisions are facilitated. These can include selection of protocols and methods, decision strategies for setting biofeedback and self-regulation parameters and characteristics, or provision of interventive activities such as voice interaction, setting thresholds, modification of the biofeedback system, or administration of therapeutic services such as electromedical, pharmaceutical, or aromatherapy.

The characteristic time delays of this control loop are on the order of time delays inherent in the human activity associated with the control and intervention. This will typically be between one and ten seconds, for typical use of remote controls. However, because this level of control incorporates a human professional as a component, delays of many days, months, or even years might be anticipated, as the system is able to provide extended, accurate, and updated therapeutic services to a subject over a long period of time and incorporates decisions and modifications that are based upon the entire extent of the subject's interaction with the system.

In the overall system, each control loop functions simultaneously with the others, providing an interactive set of concentric control systems. As a result, each level of control is maintained. While the outer levels exert a slower, modulating influence on the session, the short term processing capability is retained and operates in a stable, rapid manner. The longer term processing results are used to apply modulation, steering, configuration, and other slow, graded changes to the faster inner layers.

Referring to FIG 4, more than one remote processor may be used, and this architecture may be extended accordingly. In FIG. 4 a secondary remote device **30** with an additional remote processor is added. Additionally, the secondary remote device **30** may have its own database **39**.

The configuration of FIG. 4 offers even more flexibility. A service provider such as a health care network may utilize a plurality of secondary remote devices **30** to monitor

biofeedback sessions automatically by computer while a plurality of session monitors **18** may monitor the sessions either randomly or by scheduled access. The secondary remote devices **30** may be utilized for software upgrades of the local processor **10** as well as provide long term monitoring for analysis after a session is completed and even keep records for billing.

5 The remote database **44** serving as a mediator database can be utilized by the session monitor **18** to perform group or individual analysis which may occur during biofeedback sessions or at a later time.

With the addition of another processor and database, the configuration of FIG 4 divides the secondary remote loop into two loops. In addition to the path previously described
10 for the secondary remote loop, another loop is formed by the path **49a**, **49b** and **49c**. Because this loop has separate processing and database capabilities, it is capable of operating independently of the primary remote control loop. In this embodiment, the secondary remote input node **7** would receive data, process the data independent of the primary remote input node **5**, and through path **49c** communicate and adjust the feedback from the secondary remote
15 feedback node **8**. Thus, remote feedback node **8** may generate an output based on either the secondary remote input node **7**, the session monitor **18**, or both.

The configuration as shown in FIG. 4 also enables the session monitor **18** to work independently of the secondary remote device **30**. The communications network **14** can deliver data packets from the first-level input node **3** simultaneously to the primary remote
20 input node **5** and the secondary remote input node **7**. In addition, the secondary remote node **7** may also receive data from the primary remote node **5** across the network **14**. Additionally, the primary remote node **5** may receive data from the secondary remote node **7**. Similarly, this configuration also enables the first-level feedback node **4** to receive input from either the primary remote feedback node **6** or the secondary remote feedback node **8** independently.

25 Although the invention has been shown and described with respect to a certain preferred embodiment, it is obvious that equivalent alterations and modifications will occur to others skilled in the art upon the reading and understanding of this specification. The present invention includes all such equivalent alterations and modifications and is limited only by the scope of the following claims.
